

✓ House Price Prediction Dataset.

The dataset contains 2000 rows of house-related data, representing various features that could influence house prices. Below, we discuss key aspects of the dataset, which include its structure, the choice of features, and potential use cases for analysis.

I found this dataset in Kaggle.

1. This is a supervised regression problem in machine learning. :

Supervised Learning: The model is trained on labeled data, where each example has input features (e.g., area, number of bedrooms, bathrooms, etc.) and a corresponding target output (house price). The goal is to learn the mapping from input to output.

Regression: The task is to predict a continuous numerical value (the house price) based on the input features, which makes it a regression problem. Unlike classification, where the output is a category or class, regression predicts real-valued outputs.

Characteristics of this ML Problem: Features: Attributes such as area, bedrooms, bathrooms, floors, year built, location, condition, and garage. Target: House price (a continuous numeric value). Goal: Train a model that can predict the house price based on the given features.

We'll use supervised machine learning models to predict the house price. The steps involve:

1. Data preprocessing: Handle categorical variables, missing values, Label encoding and normalization.
2. Model selection: We can try several models, such as: Linear Regression, Decision Tree Regressor, Random Forest Regressor.
3. Model evaluation: Use metrics such as mean squared error (MSE) and R-squared to evaluate model performance.

```
#import libraries
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns
```

```
#load data
data=pd.read_csv('/content/House_Price_Prediction_Dataset[1].csv')
```

```
house=pd.read_csv('/content/House_Price_Prediction_Dataset[1].csv')
```

```

✓ Pre Processing Techniques

1. Handling Missing values

```
#Check for missing values in the dataset
missing_values=data.isnull().sum()
```

2. Label Encoding

```
#Encode Categorical variables:Location,Condition,Garage
label_encoder = LabelEncoder()
data['Location'] = label_encoder.fit_transform(data['Location'])
data['Condition'] = label_encoder.fit_transform(data['Condition'])
data['Garage'] = label_encoder.fit_transform(data['Garage'])
```

```
data
